

# Bits aren't Bites!

## Balkanizing spectrum creates scarcity

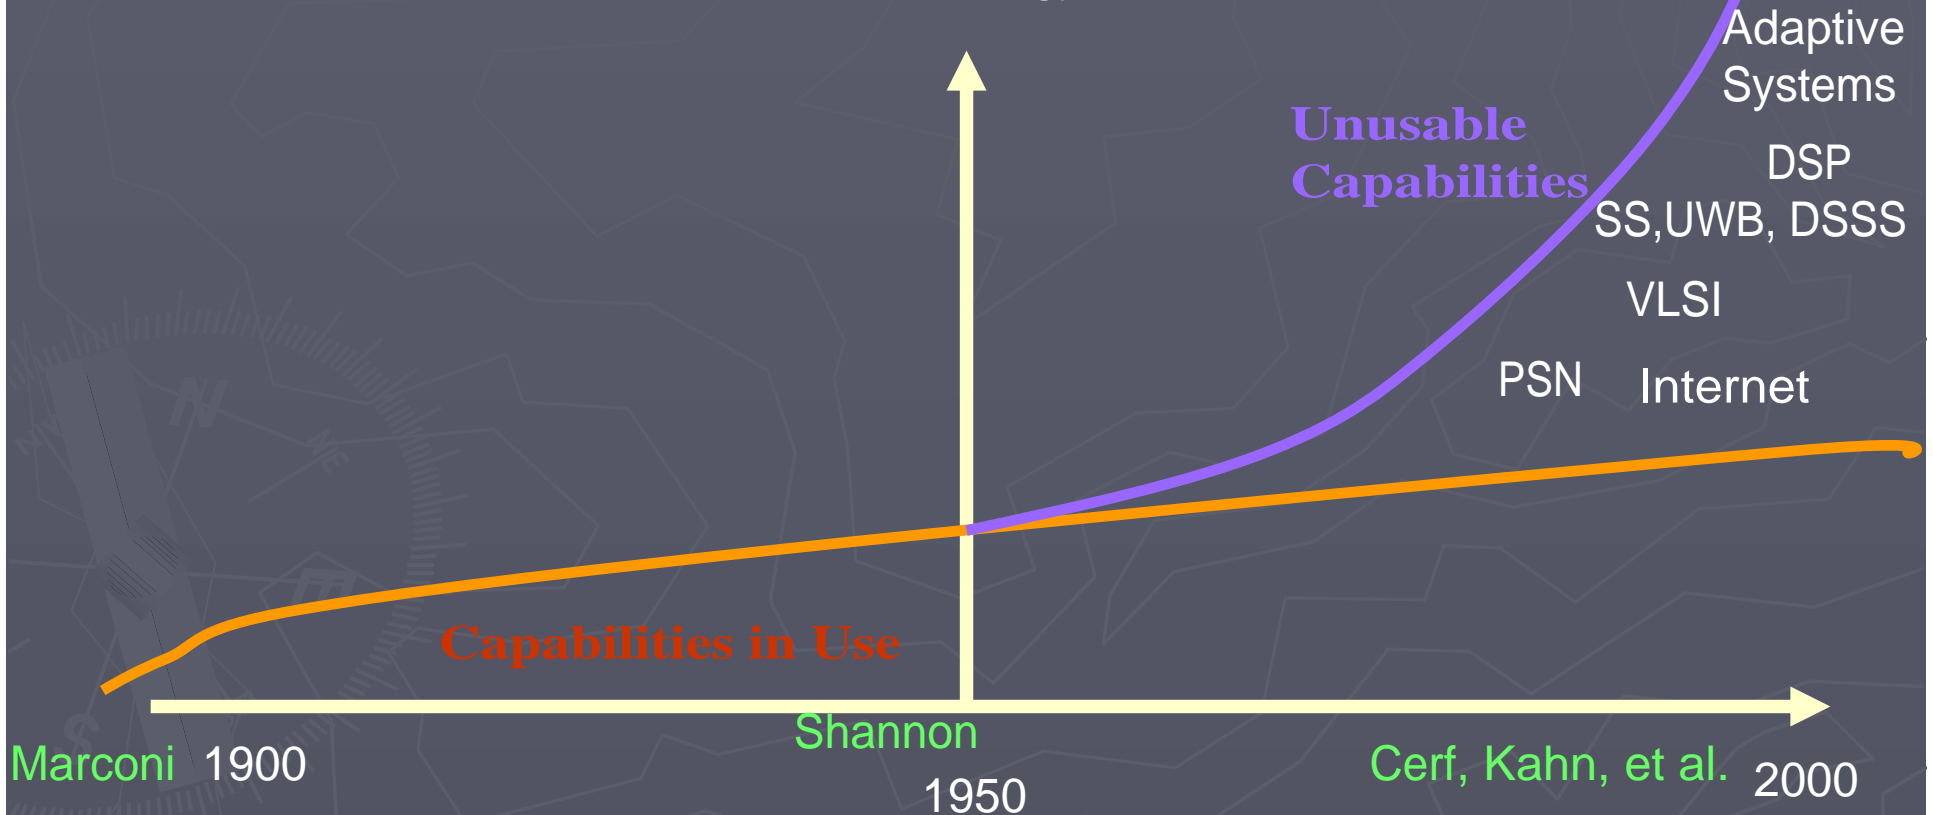

David P. Reed  
Visiting Scientist, MIT Media Lab

December 4, 2002  
Presented at MIT Wireless Forum

# Agenda

- ? Scalability matters most
- ? Does spectrum have a capacity?
  - “Spectrum, a non-depleting but limited resource” (Michael Gallagher, DoC)
- ? Interference and information loss
- ? Capacity, architecture, and scaling laws
- ? Economics and architecture

# Sustaining vs. Disruptive Technology in a Regulated Industry

Useful Wireless Communications  
Technology

# Mainframe communications vs. decentralized communications

## ? Mainframe to PC evolution

- Eliminate barriers to innovative uses
- Enable new technologies

## ? Mainframe communications to decentralized communications

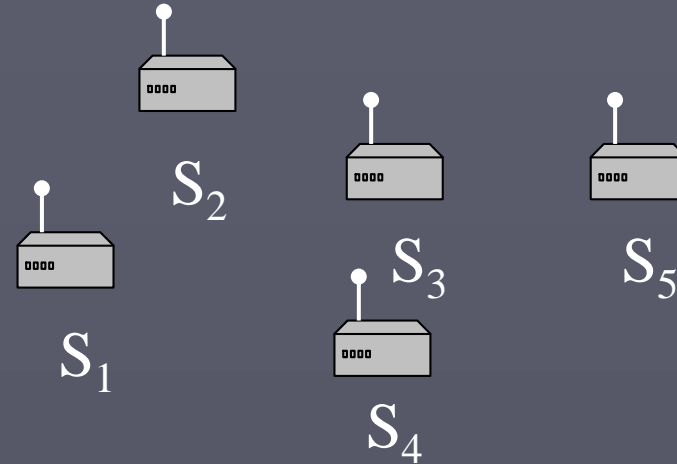

- Eliminate barriers to innovative uses (802.11)
- Enable new capabilities (pervasive C&C)

# The big problem: scalability is starting to matter

Pervasive computing  
must be wireless

Demand for connectivity  
that changes  
constantly at all time  
scales

Capacity and response  
time expectations  
evolve exponentially

# Does spectrum have a capacity?

$$C = W \log\left(1 + \frac{P}{N_0 W}\right), \text{ due to Claude Shannon}$$

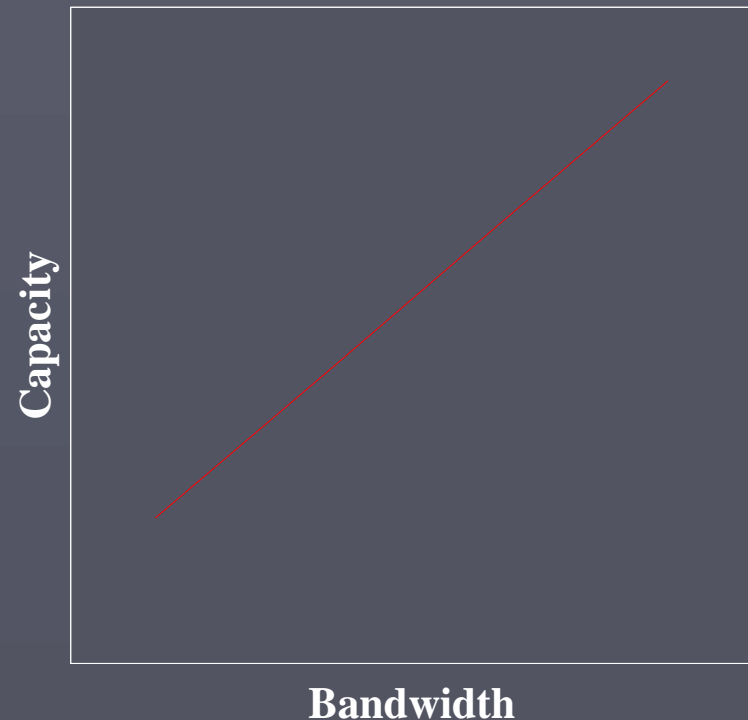

$C$  = capacity, bits/sec.

$W$  = bandwidth, Hz.

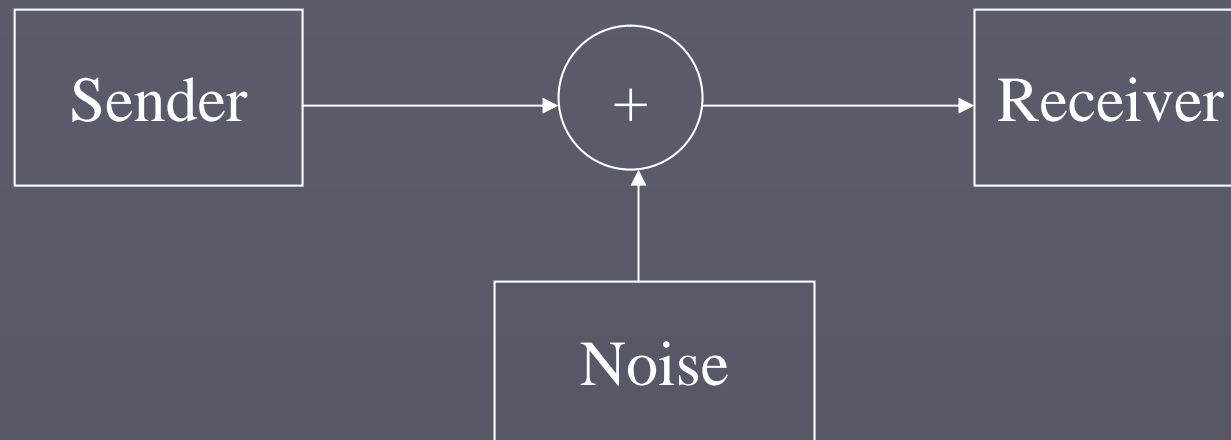

$P$  = power, watts

$N_0$  = noise power, watts.

Channel capacity is roughly  
proportional to bandwidth.

# We don't know the *full* answer.

“Standard” channel capacity is for one sender, one receiver – says nothing about the most important case: many senders, many receivers.

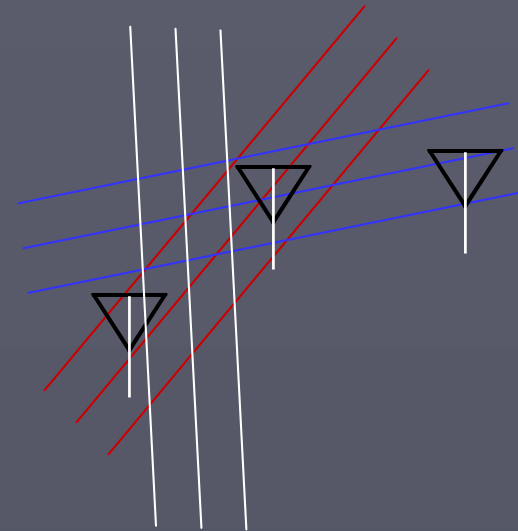

“The capacity of multi-terminal systems is a subject studied in multi-user information theory, an area of information theory known for its difficulty, **open problems, and sometimes counter-intuitive results.**”

[Gastpar & Vetterli, 2002]

# Interference and information loss

- Regulatory interference = damage
- Radio “interference” = *superposition*
- No information is *actually* lost
- Receivers may be confused
- Information loss is a systems design and architectural issue, not a physical inevitability

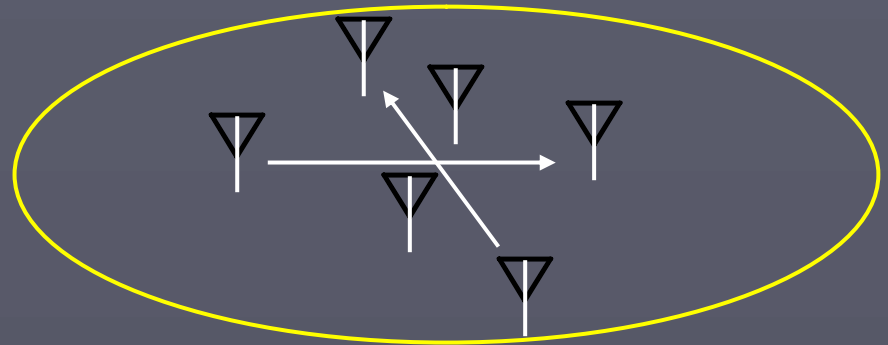

# Transport Capacity: One important measure of radio network capacity

Network of  $N$  stations  
(transmit & receive)  
Scattered in a fixed space  
Each station chooses  
randomly to send  
messages to other stations

What is total transport  
capacity,  $C_T$ , in bit-  
meters/second?

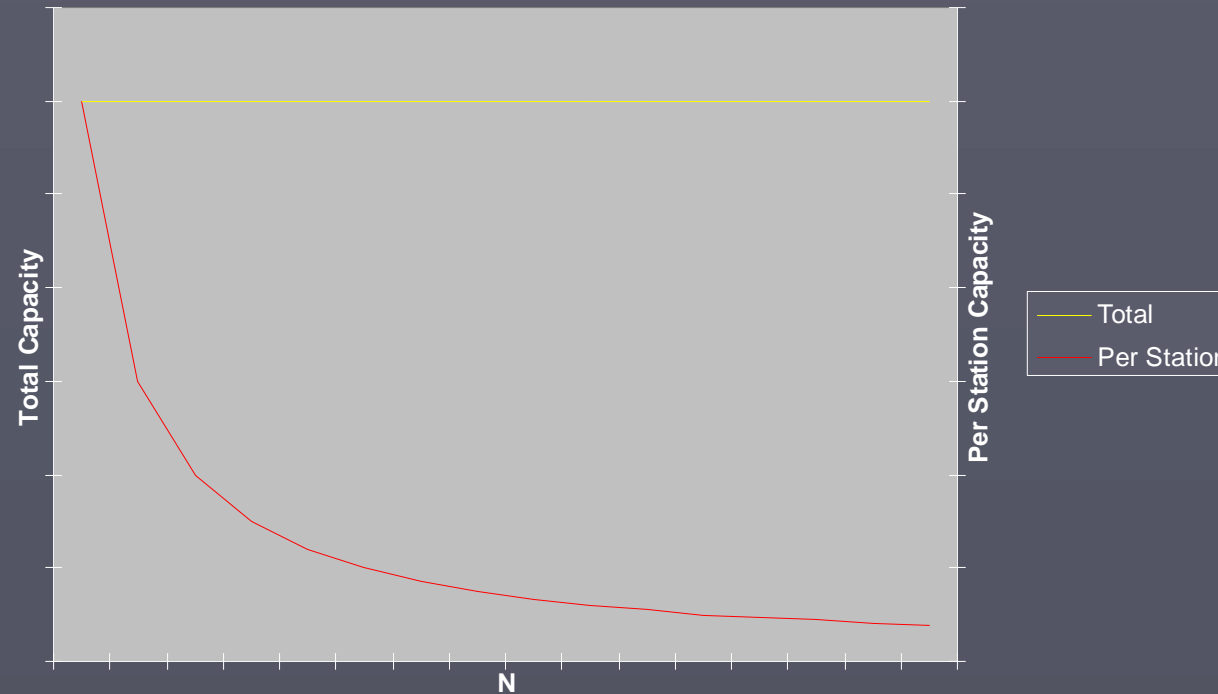

$b_{s,r}$  = bits from  $s$  to  $r$

$d_{s,r}$  = distance from  $s$  to  $r$

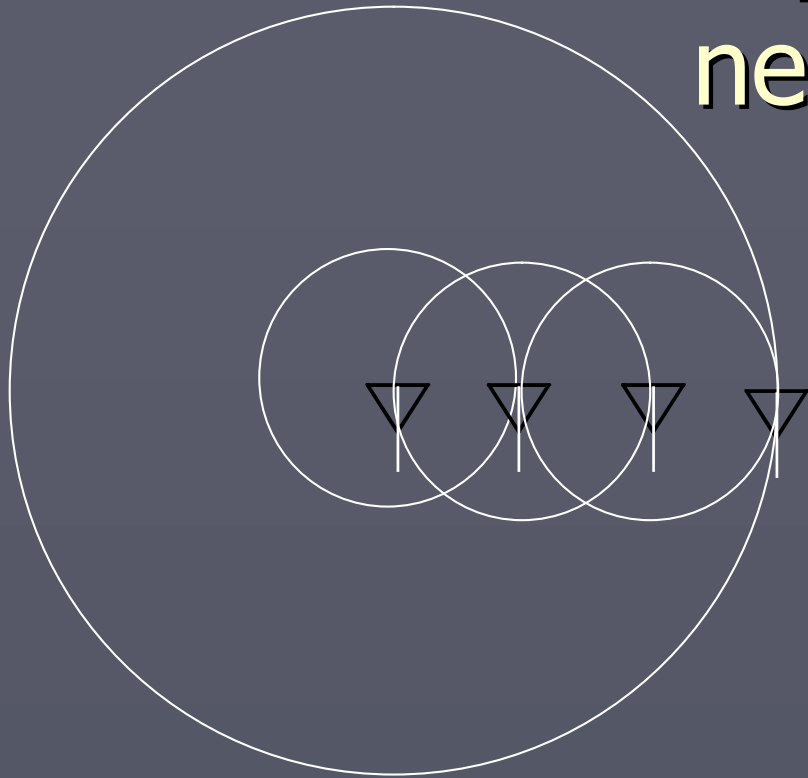

$$C_T = \frac{\sum_{s,r \in N} b_{s,r} \cdot d_{s,r}}{t}$$

# Traditional, intuitive "Spectrum capacity" model

Capacity (Bit-meters/sec) vs. Station Density

# Architectural improvement: repeater networks

Energy/bit reduced by  
 $1/\text{hops}$ .

Many paths can operate concurrently.

What is repeater network's capacity?

# Repeater Network Capacity

Capacity (Bit-meters/sec) vs. Station Density

# Architectural improvement: Spatially organized waveforms

BLAST - diffusive medium & signal processing

(“exploiting multipath”)

Cellular telephone systems

MIMO systems

Cooperative signal regeneration

# Other counterintuitive results from multiuser information theory, network architectures, and physics

Multipath increases capacity

Repeating increases capacity

Mobility increases capacity

Repeating reduces energy (safety)

Distributed computation increases battery life

Channel sharing decreases latency and jitter

# Network Capacity under Cooperation Likely to Scale w/Demand

Capacity (Bit-meters/sec) vs. Station Density

# Many economic utilities scale beneficially in network structures

Besides **total system capacity**,  
Value in terms of “**optionality**” (Real Options)  
grows:

**Flexibility in allocating capacity** to fluctuating demands  
(e.g. burst capacity proportional to total systems  
bandwidth and dispersion)

**Flexibility in “random addressability”** (e.g. Metcalfe’s  
Law)

**Flexibility in group forming** (e.g. Reed’s Law)

Dynamic **robustness** against attacks

Dynamic dispersion of signal for **physical privacy**

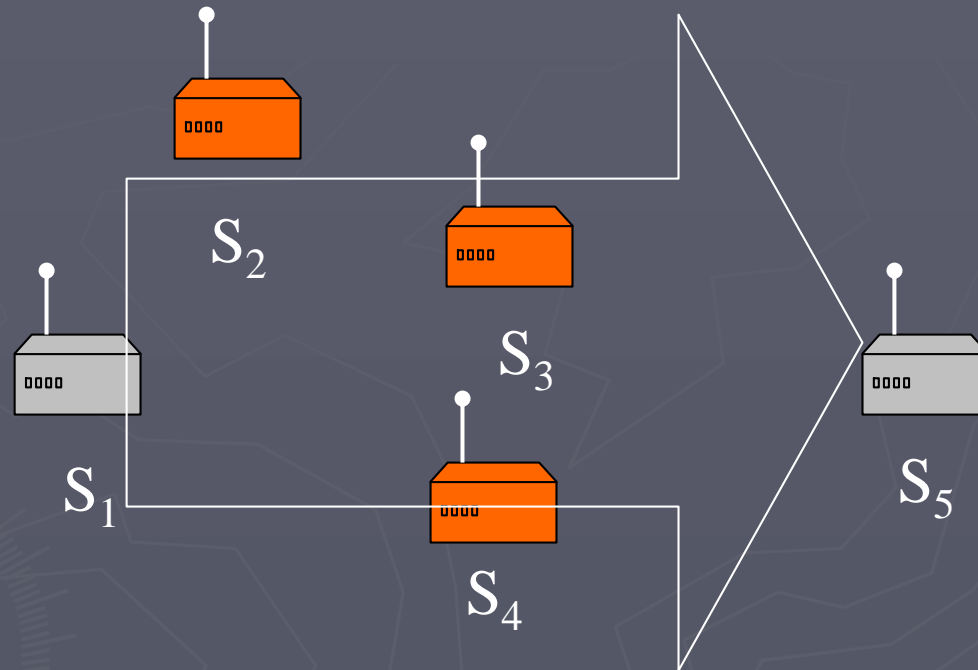

# “Cooperation gain” vs. “Tragedy of the Commons”

Markets in property rights are “solve” the “tragedy of the commons” by allocating a valuable, scarce commodity to its most valuable uses

But property rights and tragedy of commons assume the valuable commodity is conserved

Yet capacity and other economic utility of spectrum can increase with cooperation, and if proportional to  $N$ , each new user is self supporting or better.

# Cooperation vs. balkanization

Cooperation: Potential  $C_T$  proportional to  $N$ ?  
Balkanization:  $C_T$  constant or worse.

# Problems with static partitioning – “transaction cost economics”

“Guard bands” costly –  
partitioning in space,  
frequency, or time wastes  
capacity

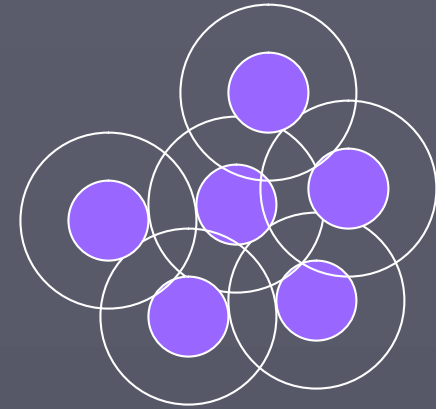

Partitioning impacts flexibility:

Burst allocation capped

Random addressability & group-  
forming value severely reduced

Robustness reduced, security  
reduced.

Space and  
Frequency  
Division

Frequency

# So what do we do?

- ? Centrally designed/regulated must become self-regulating
- ? Internetworking (no balkanization – create interoperability)
- ? End-to-end argument (hourglass model)
- ? Society of Cognitive Radios
- ? Open architecture
- ? Plan for evolution and obsolescence (no guarantees to investors)

# The end-to-end argument

- ? Implement functions at the end points or edges, if at all possible
- ? Add function in the network only if it's the only possible way to do it.
- ? (corollary: “Stupid Network”)

But why? Uncertainty about what's possible and what's useful maximizes option value.

# The hourglass model

- ? Create maximum flexibility
- ? Preserve independence of use from implementation
- ? Retain scalability
